Writing your first Linux kernel module

Praktikum Kernel Programming University of Hamburg Scientific Computing Winter semester 2014/2015

Outline

- Before you start
- Hello world module
- Compile, load and unload
- User space VS. kernel space programing
- Summary

Before you start

- Define your module's goal
- Define your module behaviour
- Know your hardware specifications
 - If you are building a device driver you should have the manual
- Documentation
 - /usr/src/linux/Documentation
 - make { htmldocs | psdocs | pdfdocks | rtfdocks }
 - /usr/src/linux/Documentation/DocBook

Role of the device driver

- Software layer between application and device "black boxes"
 - Offer abstraction
 - Make hardware available to users
 - Hide complexity
 - User does not need to know their implementation
- Provide mechanism not policy
 - Mechanism
 - Providing the flexibility and the ability the device supports
 - Policy
 - Controlling how these capabilities are being used

Role of the device driver

Policy-free characteristics

- Synchronous and asynchronous operations
- Exploit the full capabilities of the hardware
- Often a client library is provided as well
 - Provides capabilities that do not need to be implemented inside the module

Outline

• Before you start

- Hello world module
- Compile, load and unload
- User space VS. kernel space programing
- Summary

Hello world module

/* header files */
#include <linux/module.h>
#include <linux/init.h>
/* the initialization function */
static int ____init hello__init(void) {
 printk("Hello world !\n");
 return 0; /* success */
}

/* declares which function will be
invoked when the module is loaded
*/
module_init(hello_init);

/* the shutdown function */
static void __exit hello_exit(void) {
 printk("Goodbye,!\n");

/* declares which function will be
invoked when the module is
removed */
module_exit(hello_exit);

Initialization function

- Each module must use one
- Declared as static
- __init <name>
 - Use only at initialization
- __initdata
 - Mark initialization data
- Does not accept parameters
- Returns error code
- Kernel drops init function and data
 - Makes the memory available to the system

```
static int __init hello_init(void) {
  printk( "Hello world !\n");
  return 0; /* success */
}
```

module_init(hello_init);

Shutdown function

- Only if you need to unload the module
- Declared as static
- __exit <name>
 - only at shutdown
- module_exit(<name>)
- If not defined

```
static void __exit hello_exit(void) {
    printk("Goodbye,!\n");
```

module_exit(hello_exit);

- Modules can not be unloaded
- The build in modules do not require shutdown

printk

- Similar to printf but:
 - Prints to the kernel log file
 - Does not support all the formatting parameters
- Very expensive operation
 - Lots of printk's can significantly slow down the system
- Accepts loglevels
 - A hint to the kernel to decide if it should print the string to the log file
 - Default KERN_WARNING

printk - loglevels

• KERN_EMER

- An emergency condition
- KERN_ALERT,
 - requires immediate attention
- KERN_CRIT
- KERN_ERR
- KERN_WARNING
- KERN_NOTICE
- KERN_INFO
- KERN_DEBUG

Module parameters

- Pass parameters to the module through
 - insmod
 - modprobe
- modprobe reads parameters thought
 - /etc/modprobe
- Read parameter value while module is loaded
 cat sys/module/<mod_na>/parameters/<param_na>

Module parameters

- Parameter declaration
 - module_param(name, type, permission)
 - Permissions modes are as file access modes
 - Parameters types:
 - bool, inbool (inverted bool)
 - charp, string
 - int, long, short
 - uint, ulong, ushort
- Also accepts arrays parameters
 - module_param_array(name, type, nump, perm)

Error handling

- Failure may occur during initialization phase
 - memory allocation
 - device is busy
- continue or drop?
 - If we drop
 - undo any registration activities performed before
 - in case we fail to unregister the kernel goes into unstable mode
- Recovery is usually handle with the goto statement

Error handling

- Error number definitions at <linux/errno.h>
 - Return negative values -error code;

1

8

- #define EPERM #define ENOENT
- #define EIO 5
- #define ENOEXEC
- #define EAGAIN
- #define ENOMEM
- #define EACCES
- #define ENOSYS 38
- #define ENOTEMPTY 39

- /* Operation not permitted */
- 2 /* No such file or directory */
 - /* I/O error */
 - /* Exec format error */
- 11 /* Try again */
- 12 /* Out of memory */
- 13 /* Permission denied */
 - /* Function not implemented */
 - /* Directory not empty */

Outline

- Before you start
- Hello world module
- Compile, load and unload
- User space VS. kernel space programing
- Summary

Compile

• kbuild

- the system that is used to compile kernel modules
- /Documentation/kbuild/
- You must have a pre-build kernel with configuration and header files
- Many distributions have packages for the required files and tools
 - kernel-devel package for CentOS

Compile command

- make -C \$KDIR M=\$PWD [target]
 - **\$KDIR**
 - the directory where the kernel source is located.
 - make will change the directory for the compile and will return after the compile
 - M=\$PWD
 - Informs kbuild that an external module is being build.
 - The value of M is the absolute path the directory that contains the source code of the module

make command targets

modules

The default target that can be ignored

modules_install

- Installs the external modules
- The default location is /lib/modules/<kernel_release>/extra/
- clean
 - remove all generated files in the module directory only
- help
 - list the available target for the external modules

kbuild file

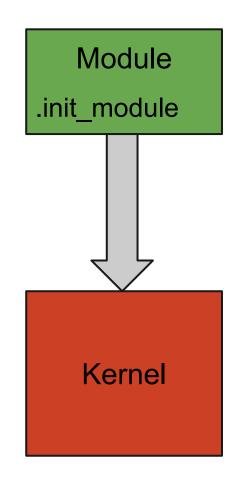

- Contains the name of the module(s) being built, along with the requisite source files
 - o obj-m := <m_name>.o
 - kbuild will build <m_name>.o from <m_name>.c
 - Then it will link it and will result in the kernel module <m_name>.ko
 - An additional line is needed to add more files
 <module name>-y := <src1>.o <src2>.o
 - Include files and directories
 - standard files using #include <file>
 - ccflags-y := -linclude_path

Module.symvers file

- Module versioning is enabled by the CONFIG_MODVERSIONS tag
- It is used as a simple Application Binary Interface (ABI) consistency check
- It contains a list of all exported symbols from a kernel build
- /proc/kallsyms

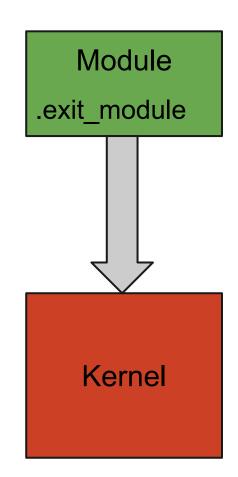

insmod (insert module)

- load the module into the kernel
 - triggers the execution of the module_init function
- Similar to the ld in user space
- Load the module code and data into the kernel memory
- Links any unresolved symbol in the module to the symbol table of the kernel
- Accepts command line arguments
 - Parameters to the kernel module
- Add an entry at /proc/modules
- For more details check kernel/module.c

rmmod (remove module)

- Removes/unloads the module from the kernel
- Must free memory and release recourse
- In case of failure the kernel still believes that the module is in use
- In case that rmmod fails the reboot process is required to clean the systems state

More tools

- Ismod (list modules)
 - List of the current loaded modules
- modprobe (similar to insmod)
 - Search for symbols that are not currently defined in the kernel
 - In case that there are then search for in kernel modules to find modules that contain these symbols
 - It loads these modules into the kernel
- depmod
 - Creates a dependency file
 - Used by modprobe
- modinfo
 - Shows information about a Linux Kernel module

Version dependency

- Modules have to be recompiled for each version
 - data structures and function prototypes can changes from version to version
 - during compilation the module is linked against a file named vermagic.o
 - This file contains target kernel version, compiler version etc.
- In case that the module is compile against different kernel version
 - insmod: Invalid module format

Version dependency (cont.)

- Macros to define kernel version during compilation found in /linux/version.h
 - UTS_RELEASE, the version of this kernel tree
 - LINUX_VERSION_CODE, binary representation of the kernel version
 - KERNEL_VERSION(major, minor, release), build an inter version code

Kernel Symbol Table

- Kernel has already exported symbols
- Loaded modules can export new symbols
 - offer their functionality to other modules
- Stack modules on top of other modules
 - Reduce complexity of the modules
 - Add flexibility to choose modules depending on the specific hardware
- Macros to export new symbols
 - EXPORT_SYMBOL(name);
 - EXPORT_SYMBOL_GPL(make);
- Expand into specific variable declarations stored in the module executable file

dkms

- Dynamic Kernel Module Support
 - Framework that enables generating Linux kernel modules whose sources generally reside outside the kernel source tree
 - Used to automatically rebuilt modules when a new kernel is installed
 - It is included in many distributions

Outline

- Before you start
- Hello world module
- Compile, load and unload
- User space VS. kernel space programing
- Summary

- kernel module programming
 - similar to event driven programming
- init function
 - says: hey I am here, I will serve your requests from now and on
- exit function
 - says: I am going to leave you.. don't bother trying to find me anymore
- Unload
 - should release any resource that the module had acquired

- kernel module runs in kernel space
 - Core of the operating system
 - Privileged operating system functions
 - Full access to all memory and machine hardware
 - Kernel address space
- User programs run in user space
 - It restricts user programs so they can't mess resources owned by other programs or by the OS kernel
 - Limited ability to do bad things like crashing the machine

- System calls Switch between user and kernel
- Memory handling
 - malloc is C library call NOT a system call
 - Use brk system call
 - Kernel allocates virtual memory area for the application
 - Lacks of memory protection
- Portability,
 - Kernel modules work with specific version and distribution of the kernel and might be platformspecific

- Kernel does not have standard headers
 - Is not linked against the standard C library
 - However, many functions are implemented inside the Linux kernel
- Cannot execute easily floating point operations
 - Floating point operations are architecture dependent
 - Usually, implemented with traps, (trigger integer to floating point mode transition)
 - In the kernel space it requires saving and restoring the floating point operations manually
- Small fixed size stack
 - Configurable at compile time (4KB or 8KB)

Outline

- Before you start
- Hello world module
- Compile, load and unload
- User space VS. kernel space programing
- Summary

Summary

- Role of the Device Driver
 - Mechanism VS. Policy
- How to write a dummy kernel module
 - o initialization, exit function
 - Makefile
- Tools to handle kernel modules
 - insmod, rmmod, Ismod, modprobe
- Differences between User and Kernel programming

Music album as LKM

- Band releases album as Linux kernel module
